Savior Glass

An offline, Bangla-first assistive smart glass for visually impaired people

MD Abdun Fattah Lam (2220014) · Mukut Protim Memo (2020086) · Tanjila Hossain Tapti (2130561)

Supervisor: Mohammad Shidujaman, PhD, Assistant Professor

Department of Computer Science and Engineering, Independent University, Bangladesh · Spring 2026

Reading, recognising and paying still need a helper

A blind person buys medicine and receives change. To know what the label says, which note came back and whether it is real, they must ask someone, and they cannot check the answer.

2.2 billion

people live with some form of vision impairment (WHO)

Built for English

Existing devices do not read Bangla or know Taka notes.

Need internet or money

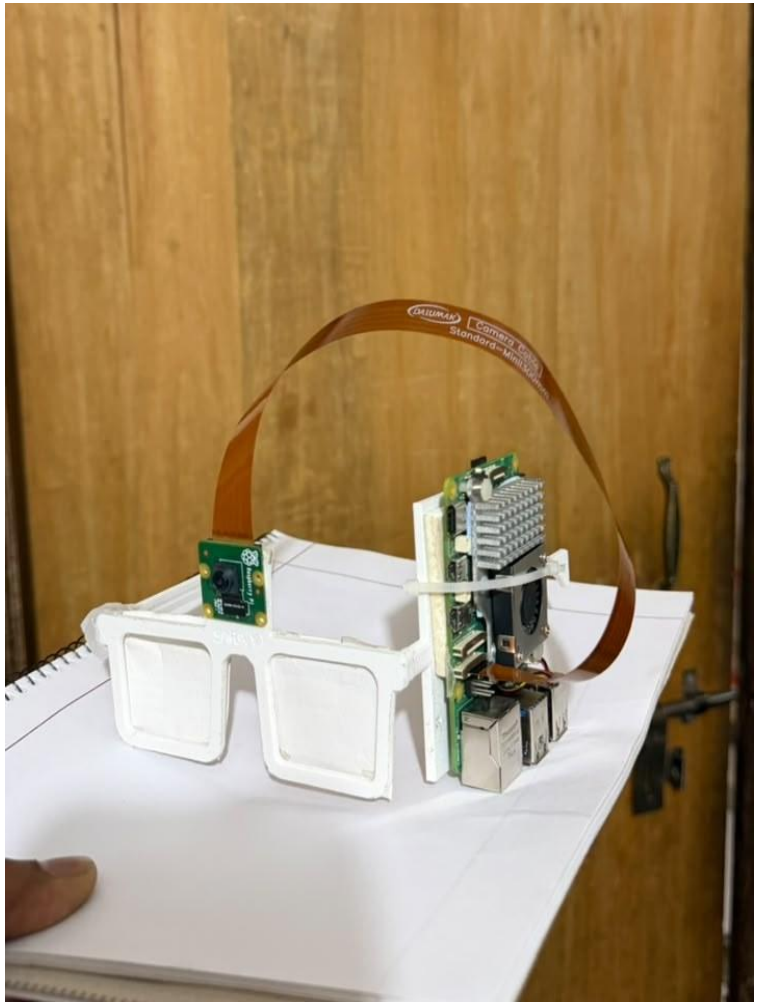

Many send pictures to a server or need a phone and a paid service.

Answers cannot be checked

A wrong note or a false "counterfeit" costs money or causes an accusation.

Savior Glass: five modes, five buttons, Bangla speech

Text reading

Bangla and English OCR, spoken right after capture

Objects

Names objects in front of the user every 1.5 s

Currency

All nine Taka notes, with a cautious counterfeit check

Emotion

Facial expression of the person in front

Online description

Optional; the only mode that needs the internet

Controlled by MODE, ACTION, READ and two volume buttons. Every change is spoken.

Six research questions

1

System

Can a multi-function Bangla glass run on a Raspberry Pi 5, and how fast?

2

Synthetic data

Can a Taka detector trained without hand labels work on real photographs?

3

Number of views

Why do multi-view counterfeit models fail with fewer views, and can training fix it?

4

Unseen prints

How much does accuracy drop on counterfeit prints never seen in training?

5

Safety

Can the glass give counterfeit advice that never accuses a genuine note?

6

Bangla OCR

Which part of a Bangla OCR pipeline matters most for a wearable camera?

What existing devices miss

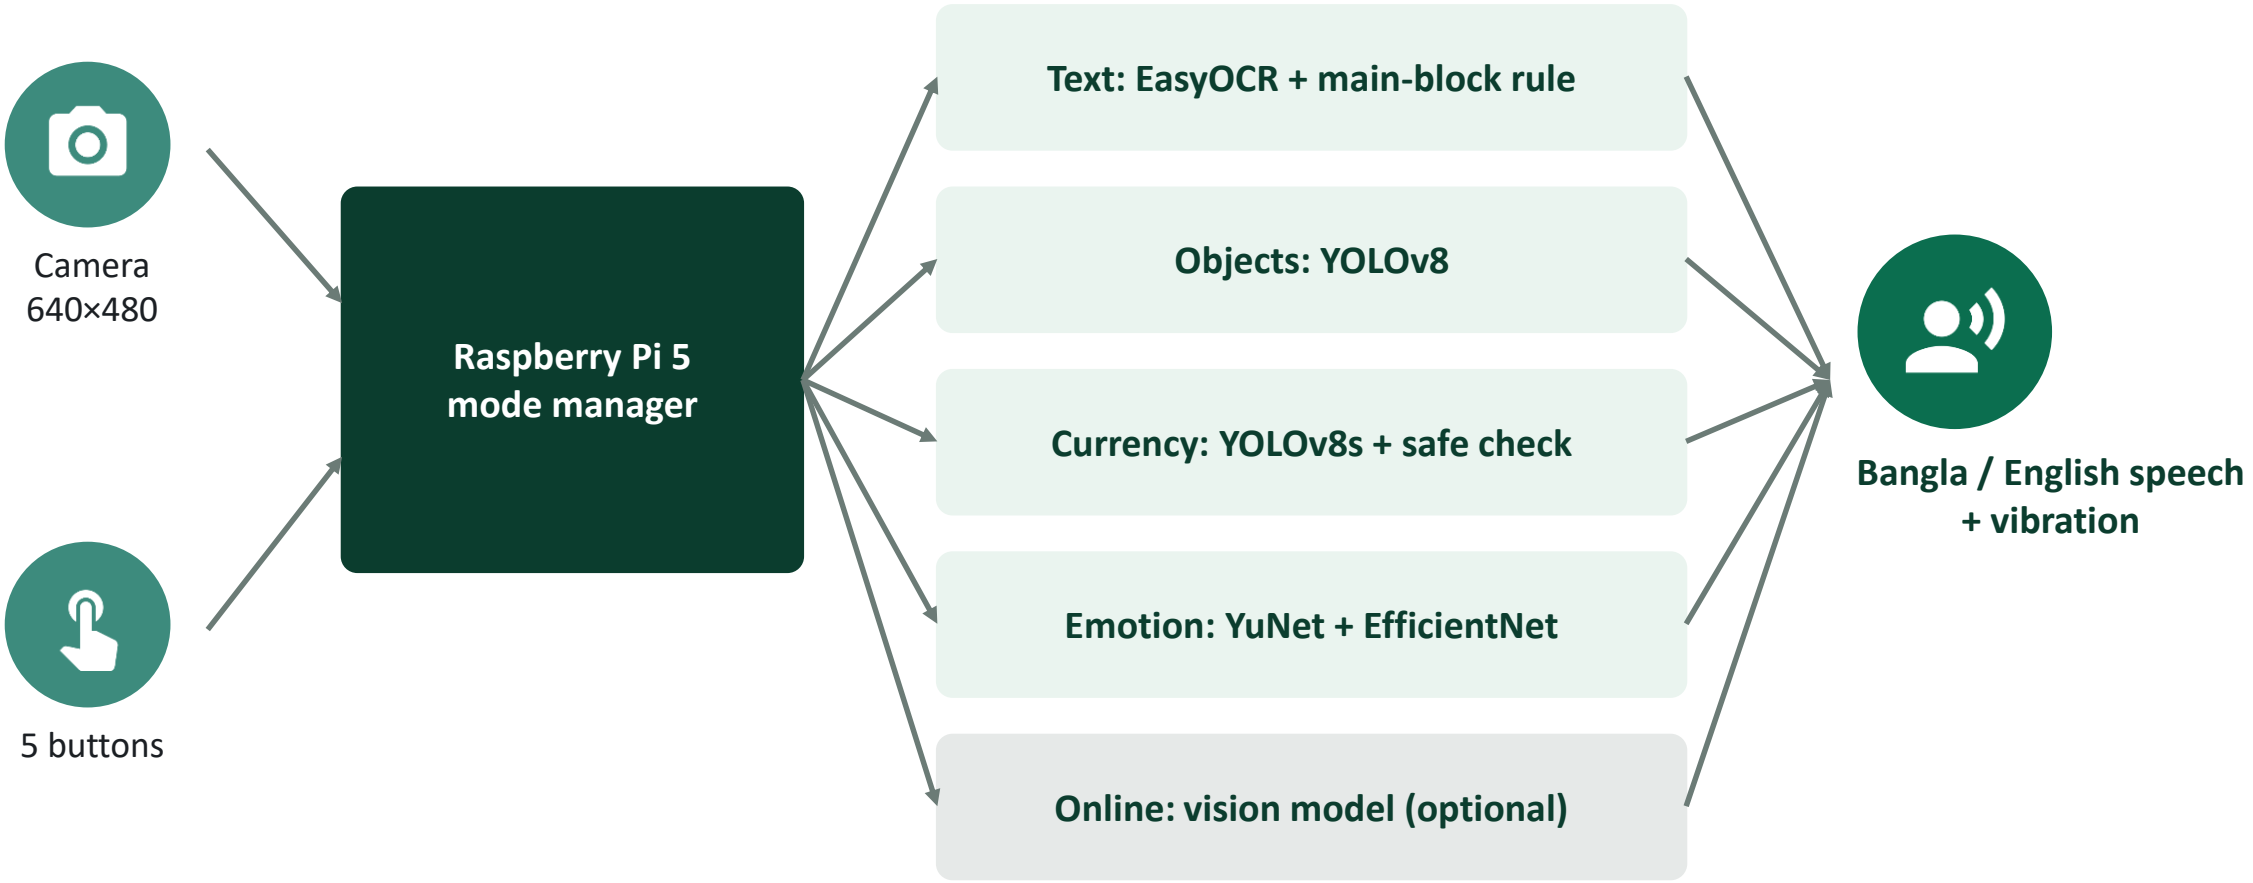

System	Reads Bangla	Knows Taka	Works offline	Wearable
OrCam MyEye	No	No	Yes	Yes
Google Glass scene analysis	No	No	No	Yes
AIris (2024)	No	No	No	Yes
Raspberry Pi reading aids	No	No	Partly	Partly
Savior Glass (ours)	**Yes**	**Yes**	**Yes**	**Yes**

Online: the online description mode needs the internet; the other four modes do not.

The gap

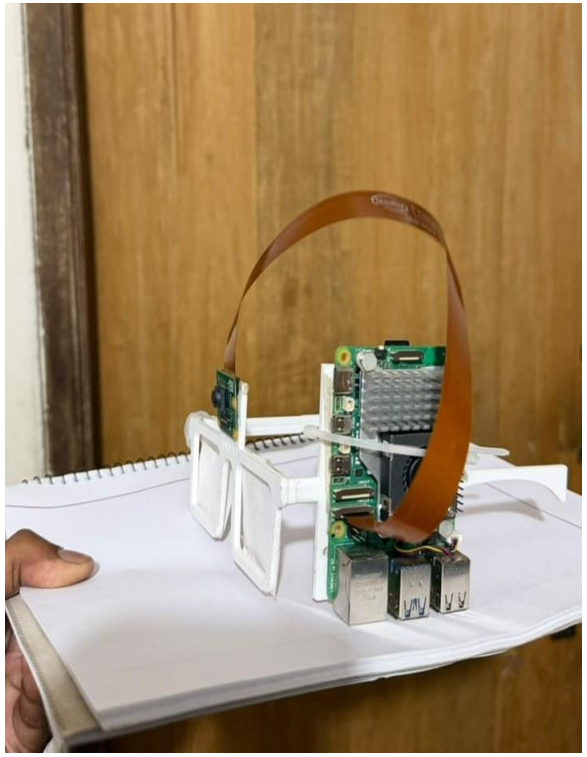

No device combines Bangla, Taka and offline use. Counterfeit studies never check whether test notes are copies of prints seen in training.

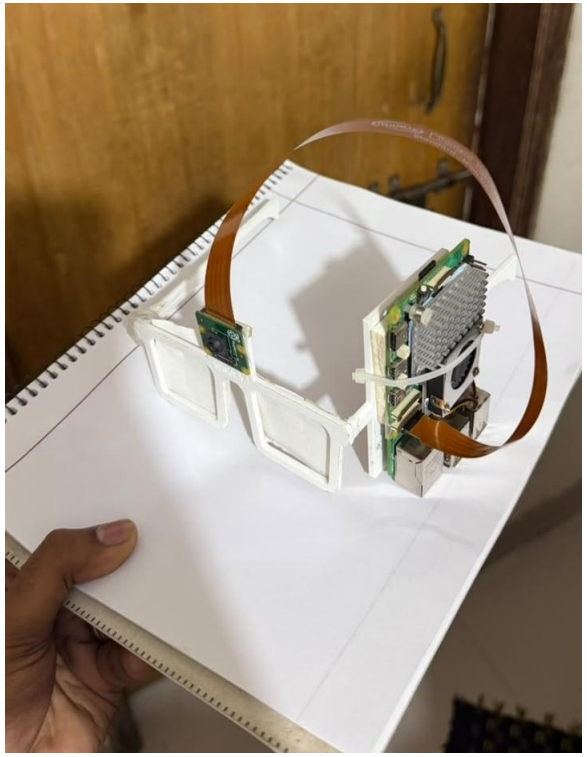

How the glass works

All models run on the Pi's CPU. Every event is written to a small CSV field log for later study.

From design to a first prototype

- Camera above the bridge of a 3D-printed frame
- Raspberry Pi 5 with fan tied to the right temple
- Ribbon cable loops from camera to board
- Next: board, buttons and battery in a pocket enclosure

The first prototype is heavy on one side and the fan sits by the ear. It is enough to test the software on a person.

Taka detection: 22,333 training images, no hand labels

5,073 note photos are pasted onto real COCO pictures with random angle, scale, light and blur. The program writes the box labels itself.

0.995

mAP@0.5 on 2,282 held-out composites

91.5%

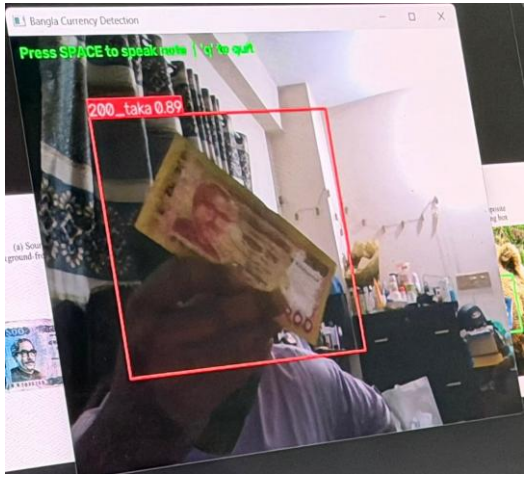

correct on 1,536 photos taken by others

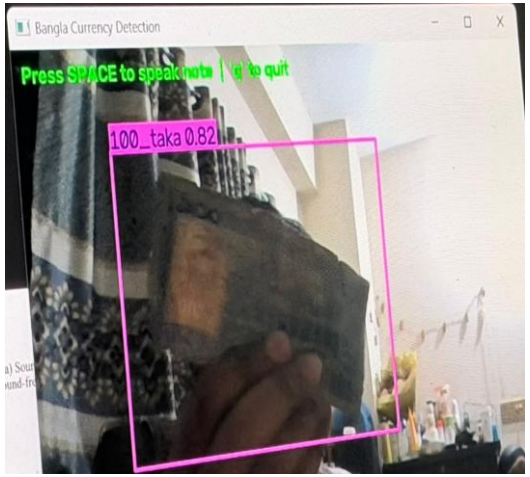

18.5%

on hand-held close-ups: still a weak point

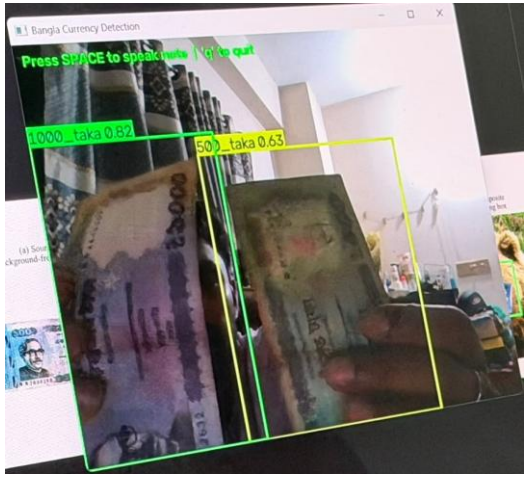

Live test with real notes

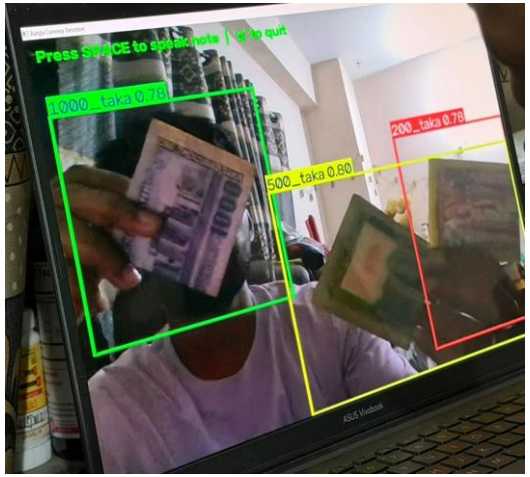

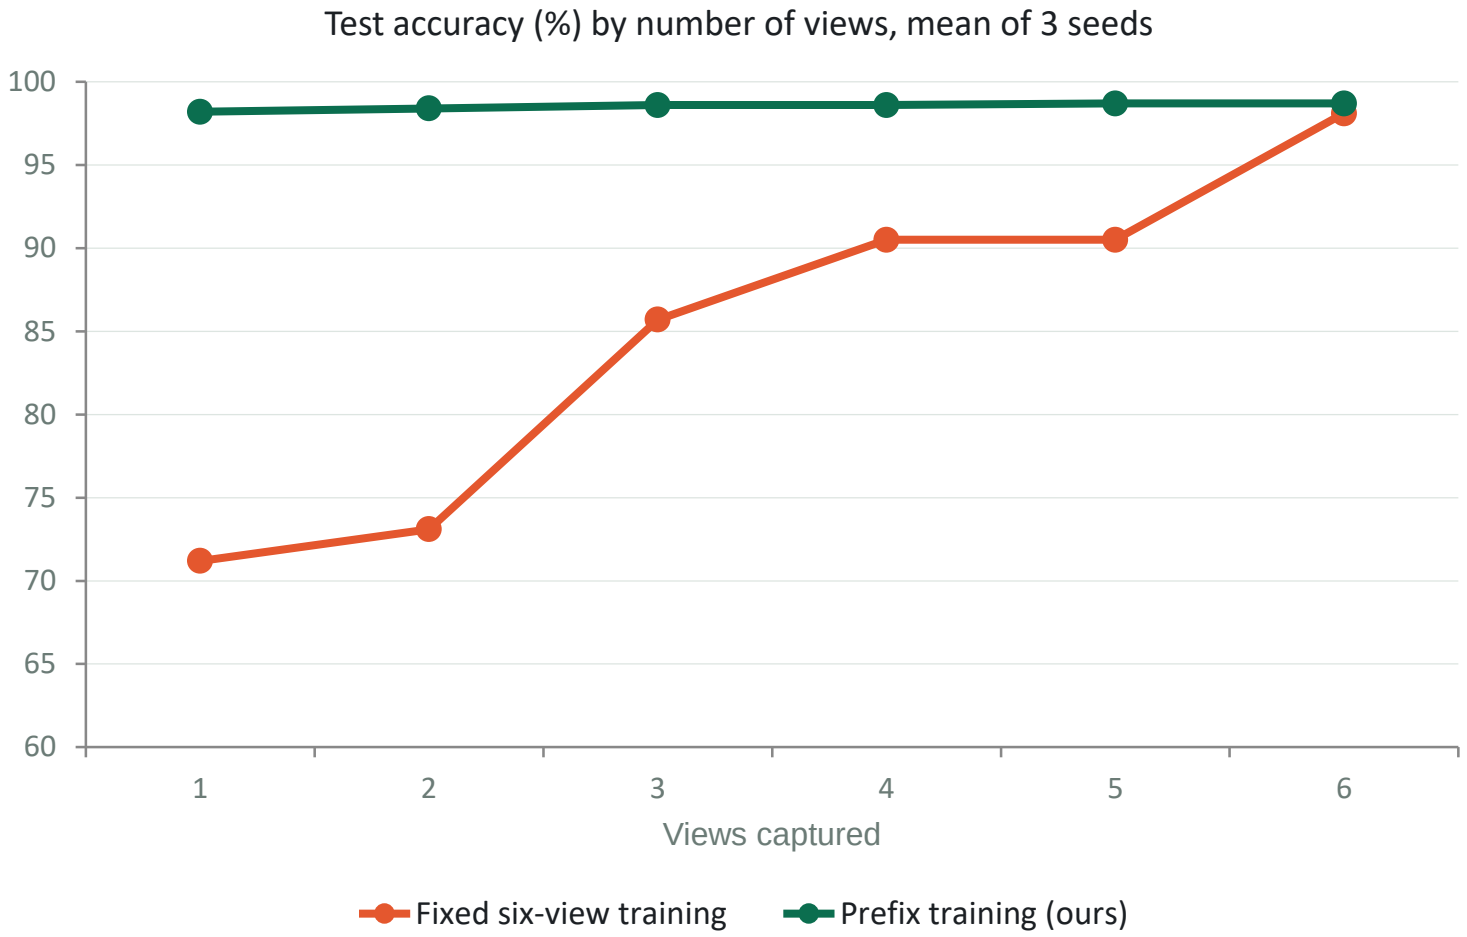

- 10, 50, 100, 200, 500 and 1,000 Taka named at 0.63–0.89 confidence
- Works on worn and folded notes and with two or three notes at once
- Boxes are loose and can overlap when notes are close

Informal sessions with a laptop webcam; no error rate was counted.

Counterfeit check: one view is enough with prefix training

71.2% → 98.2%

accuracy with a single view, JaalTaka, 3 seeds

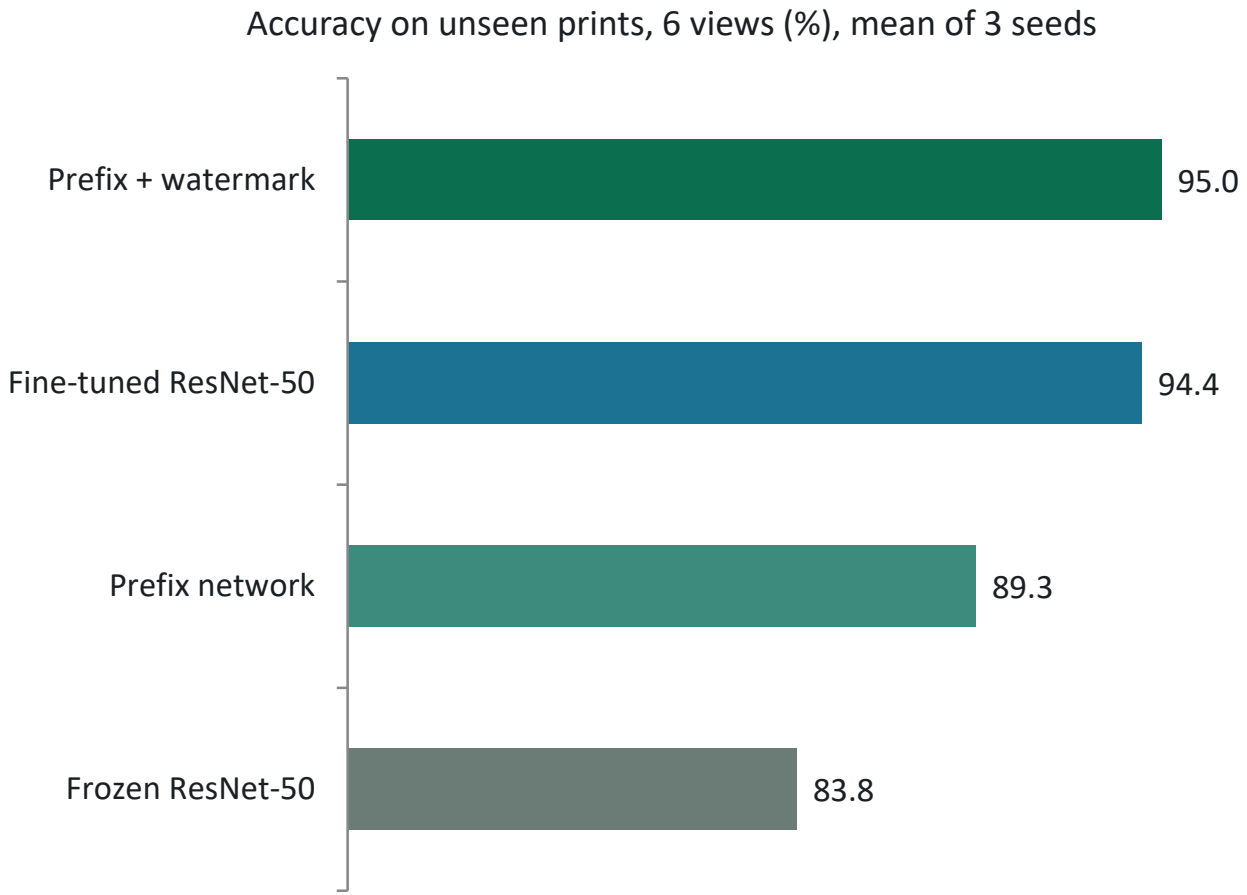

- A blind user cannot promise six views
- Training on random first-k views removes the collapse
- No loss at six views; stable across seeds

Unseen counterfeit prints: the honest test

279 of 322

readable 500 Taka counterfeits carry the same serial number

The usual split puts copies of one print in training and test. A serial lookup alone scores 90.2%. We built a split where every test counterfeit is a new print.

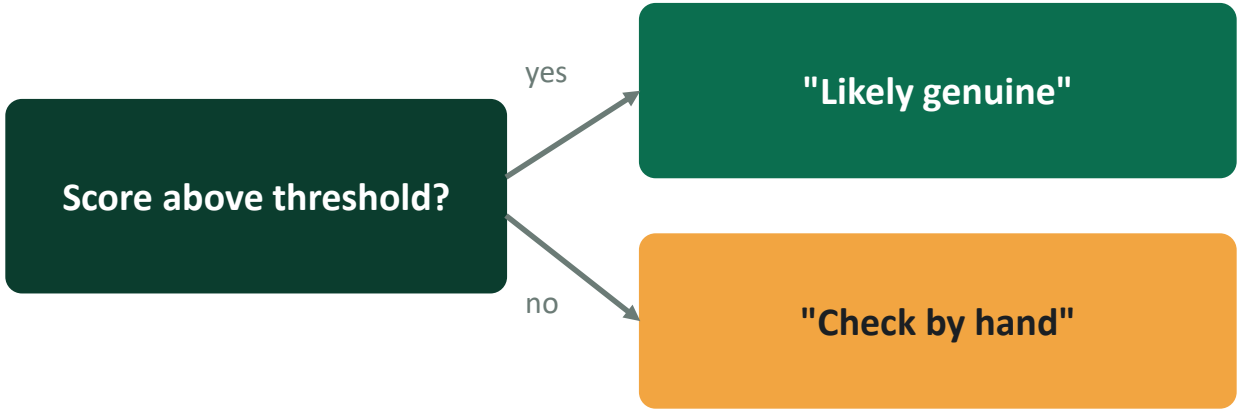

The watermark brings accuracy back to 95%, level with a fine-tuned ResNet-50. With about 24 test prints we claim a tie, not a win.

Safe before decisive: the glass never says "counterfeit"

0 / 88

test counterfeits passed as "likely genuine"

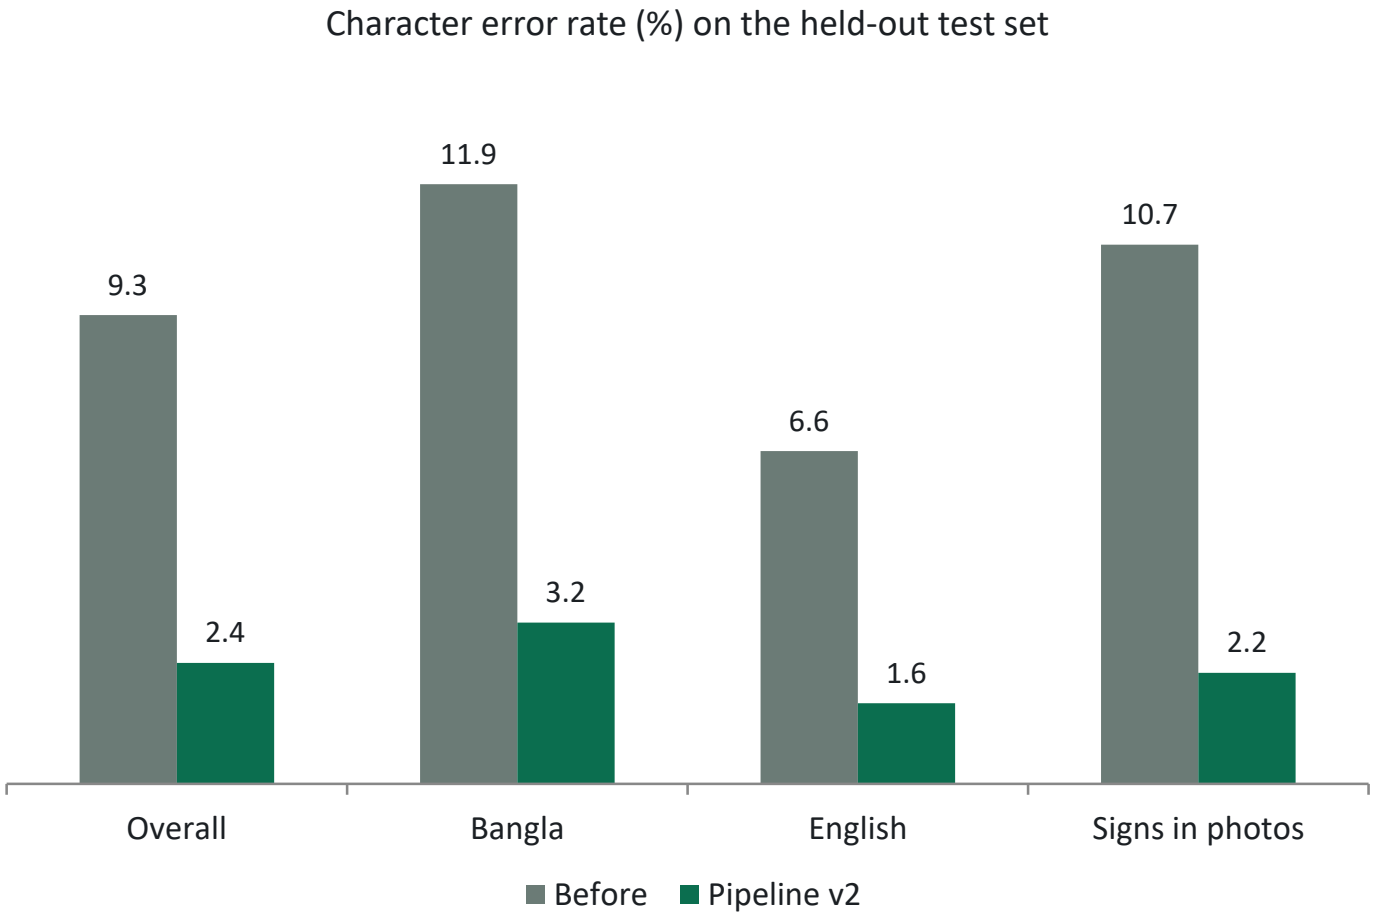

Threshold = highest score of any validation counterfeit, so a new counterfeit passes with probability 1/(n+1) = 1.1%.

The price of safety

On close-up views 57.5% of genuine notes are confirmed, but on whole-note photos only 0.4–2%. Most notes go to "check by hand".

Bangla reading: error cut by three quarters

What helped

- Reading only the main block of text
- Tuned detector settings, CLAHE
- Simple clean-up rules

What did not

- Binarisation, multi-scale reading
- Tesseract, TrOCR, PaddleOCR
- Dictionaries and language models

Benchmark with correctly shaped Bangla; every choice made on validation data.

Running on the Raspberry Pi 5

327 ms

currency check, median

50 ms

watermark check

207 ms

object scan

18.7 s

text reading: too slow

77.1 °C

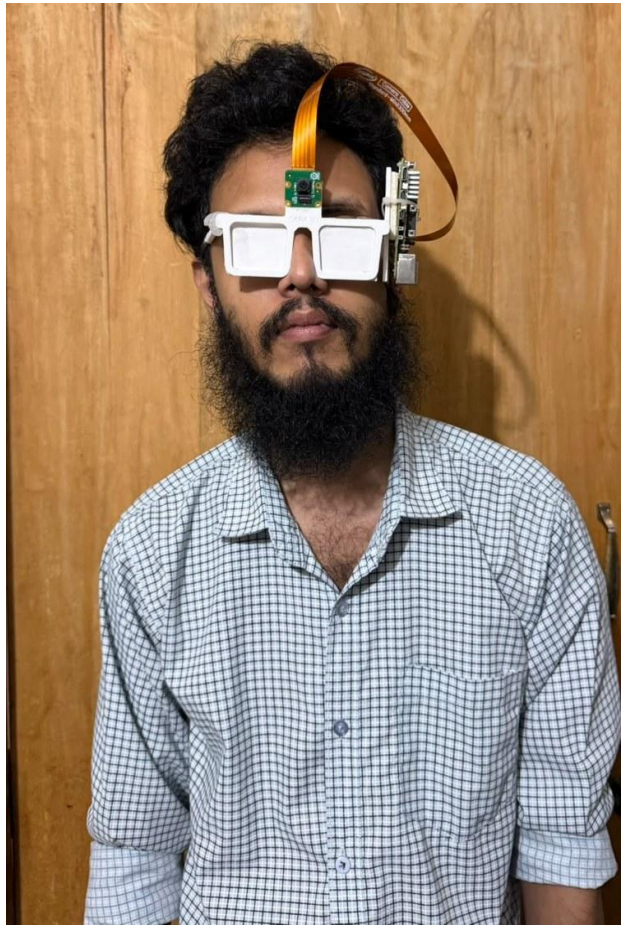

peak, no throttling in 30 min

1.48 GB

peak memory

Testing the worn glass

First field test

With the glass camera, currency was unreliable and Bangla text was not read. We suspect the 640×480 fixed-focus picture; the laptop webcam works.

Trials and survey

Sessions with a visually impaired participant have started. A Bangla voice questionnaire records answers; results will follow.

Limitations we report openly

Glass camera

Lab results not yet reproduced on the worn device

User study

Trials started; no results reported yet

Few counterfeit prints

About 24 unseen prints: ±12 points uncertainty

Slow OCR on the Pi

About 19 s per capture

Close-ups and unknown notes

18.5% on hand-held close-ups

Battery life

Not measured yet

Next steps

1

Fix the glass camera

Higher resolution or autofocus; test set taken through the glass

2

Run the user study

8–12 participants: task time, accuracy, SUS and NASA-TLX

3

Collect more prints

About 100 unseen counterfeit prints with a bank or the police

4

Faster reading

Lighter text detector; fine-tune on real photos

5

Pocket enclosure

Move board, buttons and battery off the frame; measure battery

Thank you

Questions are welcome

- A Bangla-first glass that reads, names objects and recognises Taka on a Raspberry Pi 5
- Honest tests: unseen prints, a safe verdict, correctly shaped Bangla
- Next: make it work through the glass camera and with users
